

**FIRST RECORD OF THE GENUS *NEOMICRODISPUS*
(ACARI: MICRODISPIDAE) FROM RUSSIA WITH THE DESCRIPTION
OF A NEW SPECIES AND A KEY TO WORLD GENERA
OF THE FAMILY MICRODISPIDAE**

Alexander A. Khaustov

Tyumen State University, Tyumen, Russia
e-mail: alex1973khaustov@gmail.com

ABSTRACT: *Neomicrodispus sibirensis* sp.n. (Acari: Microdispidae), collected from a decaying tree stump in Western Siberia, Russia, is described. After studying the type material for *Neomicrodispus iranicus* Hajiqanbar et Hosseininaveh, 2014, the diagnosis of the genus *Neomicrodispus* Hajiqanbar et Hosseininaveh, 2014 was modified. In addition, a key to the world genera of the family Microdispidae is provided.

KEY WORDS: Mites, Heterostigmata, systematics, Western Siberia, SEM microscopy.

DOI: 10.21684/0132-8077-2018-26-2-175-182

INTRODUCTION

The family Microdispidae Cross, 1965, which currently includes 27 genera and more than 120 species, is the least diverse and the least studied family of pygmephoroid mites (Khaustov 2017; Khaustov *et al.* 2018; Khaustov and Ermilov 2018; Khaustov and Frolov 2018; Azhari *et al.* 2018). Most microdispid mites are fungivorous, but some species are parasitoids of insects (Kaliszewski *et al.* 1995). Many microdispid species are incompletely described, and their taxonomic position is unclear (Khaustov 2017). A lack of a key to the genera of the family Microdispidae causes problems with the correct placement of many species in their proper genera. The previous key to the genera of the family Microdispidae was published by Mahunka (1970). Since that time, many microdispid genera have been described or redefined (Mahunka 1972, 1975, 1977a, b, 1978; Kaliszewski and Rack 1986; Mahunka and Mahunka-Papp 1994; Khaustov 2006, 2009, 2014; 2017; Hajiqanbar and Hosseininaveh 2014; Khaustov and Tolstikov 2015; Khaustov and Minor 2016; Khaustov and Zelalem 2017; Azhari *et al.* 2018; Khaustov *et al.* 2018; Khaustov and Ermilov 2018). In this paper, I provide a key to the world genera of Microdispidae.

During my study of heterostigmatic mites of Western Siberia, I recorded a new species *Neomicrodispus sibirensis* sp.n. that belongs to a rare genus. After studying the type material of *Neomicrodispus iranicus* Hajiqanbar et Hosseininaveh, 2014, I concluded that the original description of *Neomicrodispus iranicus* lacks some important taxonomic characters. Consequently, this paper contains a modified diagnosis of the genus *Neomicrodispus*.

MATERIAL AND METHODS

The mites were collected from samples taken from a decaying tree stump, using Berlese funnels and mounted in Hoyer's medium. The holotype and one paratype of *Neomicrodispus iranicus* were loaned from the collection of Tarbiat Modares University (Tehran, Iran). Mite morphology was studied using a Carl Zeiss AxioImager A2 compound microscope, equipped with a phase contrast and DIC objectives. For SEM microscopy, alcohol-preserved mites were freeze-dried in JFD 320 (JEOL, Japan), coated in gold, and then scanned with the aid of a JEOL JSM-6510LV SEM microscope.

The terminology of the idiosoma and legs follows that of Lindquist (1986); the nomenclature of subcapitular setae and the designation of cheliceral setae follow Grandjean (1944, 1947), respectively. The taxonomic system of Pygmephoidea follows that of Khaustov (2004, 2008). All measurements for the holotype and five paratypes (in parentheses) are provided in micrometers (μm). For leg chaetotaxy, the number of solenidia is provided in parentheses.

RESULTS

Family Microdispidae Cross, 1965

Genus *Neomicrodispus* Hajiqanbar et Hosseininaveh, 2014

Type species: *Neomicrodispus iranicus* Hajiqanbar et Hosseininaveh, 2014, by original designation.

Diagnosis. As in Hajiqanbar and Hosseininaveh (2014), with the following modifications.

Gnathosoma. Postpalpal setae (*pp*) present.

Idiosomal venter. Setae *4a* present or absent.

Legs. Setation of tibiotarsus I – 15(3) (*d, l', l'', v', v'', k, tc', tc'', ft', ft'', p'', pl', pl'', pv', pv'', ω₁, φ₁, φ₂*). Tibia IV without solenidion.

Neomicrodispus sibiricensis sp.n.

(Figs. 1–4)

Description. Female (Figs. 1–4). Length of idiosoma 175 (165–175), width 110 (100–110).

Gnathosoma. Length of gnathosoma 22 (22–23), width 13 (12–14). Dorsal median apodeme absent. Cheliceral setae *cha* 13 (12–13) weakly barbed and pointed (Figs. 4B–D). Postpalpal setae (*pp*) needle-like, located laterally to bases of *cha* (Fig. 4D). Setae *dFe* and *dGe*, smooth, pointed, subequal. Subcapitular setae *m* 8 (8–9) smooth and pointed. Accessory setigenous structure (*ass*) short, cylindrical. Subcapitulum with oval pits in posterior part. Pharyngeal pump I small, bow-shaped, smooth, distinctly separated from large subrectangular and transversely striated pump II; pharyngeal pump III small, smooth, located just behind pump II.

Idiosomal dorsum (Fig. 1A). Prodorsum only slightly covered by anterior part of tergite C. All dorsal shields with numerous very small round dimples. All dorsal hysterosomal setae sparsely barbed and pointed. Trichobothria with long stem, clavate, weakly barbed, with two short apical projections. Cupules *ia* and *ih* small, round. Posterior parts of tergites C, D, EF and lateral plates with row of u-shaped elevations. Tergite C with two pairs of oval porous areas medially to setae *c₁* and one pair laterally to *c₂*; tergite EF with one pair of round porous areas just anterior to bases of setae *e*; tergite H with one pair of porous areas medially to setae *h₁*. Posterior margin of tergite H with short and wide u-shaped projection. Lengths of dorsal setae: *sc₂* 26 (24–29), *c₁* 38 (34–39), *c₂* 37 (34–38), *d* 40 (40–43), *e* 38 (37–39), *f* 42 (41–46), *h₁* 35 (35–37), *h₂* 23 (23–25). Distances between setae: *sc₂–sc₂* 36 (35–37), *c₁–c₁* 45 (42–46), *c₁–c₂* 22 (21–23), *d–d* 21 (20–22), *e–f* 21 (19–22), *f–f* 23 (21–23), *h₁–h₁* 35 (33–35), *h₁–h₂* 11 (10–11).

Idiosomal venter (Figs. 1B, 4A, B, E). Apodemes 1 (ap1), apodemes 2 (ap2) and sejugal apodeme (apsej) well developed and joined with prosternal apodeme (appr); apodemes 3 (ap3) weak, linear, joined with poststernal apodeme (appo); apodemes 4 (ap4) well developed, reaching beyond bases of setae *3b*. Apodemes 5 absent. Ventral plates with

numerous very small round dimples. All ventral setae pointed. Setae *3b, 4a* and *4b* smooth; setae *3a, 3c, 4c* and *ps₁–₃* with few weak barbs; other ventral setae distinctly barbed. Posterior part of poststernal plate and aggenital plate with u-shaped elevations. Posterior margin of posterior sternal plate weakly convex in middle part. Posterior margin of aggenital plate almost straight. Anterior (ags) and posterior (pgs) genital sclerites small, bell-like. Lengths of ventral setae: *1a* 21 (21–23), *1b* 18 (18–20), *2a* 28 (24–29), *2b* 30 (30–32), *3a* 24 (24–25), *3b* 30 (25–30), *3c* 22 (22–23), *4a* 27 (27–30), *4b* 44 (44–46), *4c* 35 (35–37), *ps₁* 13 (11–13), *ps₂* 12 (11–12), *ps₃* 13 (12–13).

Legs (Figs. 2, 3, 4F). Leg I (Figs. 2A, 4F). Lengths of solenidia *ω₁* 9 (9–10), *φ₁* 6 (6), *φ₂* 6 (6); *φ₁* clavate, *ω₁* finger-shaped, *φ₂* uniformly thin. Setae *l'* of femur and *k* of tibiotarsus blunt-ended; other leg setae (except eupathidia) pointed. Seta *v'* of trochanter smooth; other leg setae (except eupathidia) barbed. Leg II (Fig. 2B). Tarsus with claws distinctly thickened in basal part and with flipper-like empodium. Solenidion *ω* 7 (7–8) finger-shaped, solenidion *φ* 3 (3) weakly clavate. All leg setae pointed and barbed. Leg III (Fig. 3A). Claws and empodium as on tarsus II. Solenidion *φ* 2 (2) weakly clavate. All leg setae pointed and barbed. Leg IV (Fig. 3B). Tarsus with simple hooked claws and small empodium. All leg setae pointed and barbed.

Male and larva unknown.

Differential diagnosis. The new species can be distinguished from *N. iranicus* by the presence of setae *4a* (absent in *N. iranicus*) and distinctly longer dorsal hysterosomal setae.

Type material. Female holotype, slide ZISP T-Mcd-002, Russia, Tyumen Region, vicinities of lake Kuchak, 57°21' N, 66°03' E, in a decaying stump, 1 August 2018, coll. A.A. Khaustov; paratypes: 8 females, same data; 2 females, same locality, 26 September 2018.

Type deposition. The holotype and two paratypes are deposited in the collection of the Zoological Institute of Russian Academy of Sciences (St. Petersburg, Russia), other paratypes in the collection of the Tyumen State University Museum of Zoology, Tyumen, Russia.

Etymology. The name of the new species refers to its distribution in Siberia.

Neomicrodispus iranicus Hajiqanbar et Hosseininaveh, 2014

Neomicrodispus iranicus Hajiqanbar et Hosseininaveh, 2014, p. 2, Figs. 1–5.

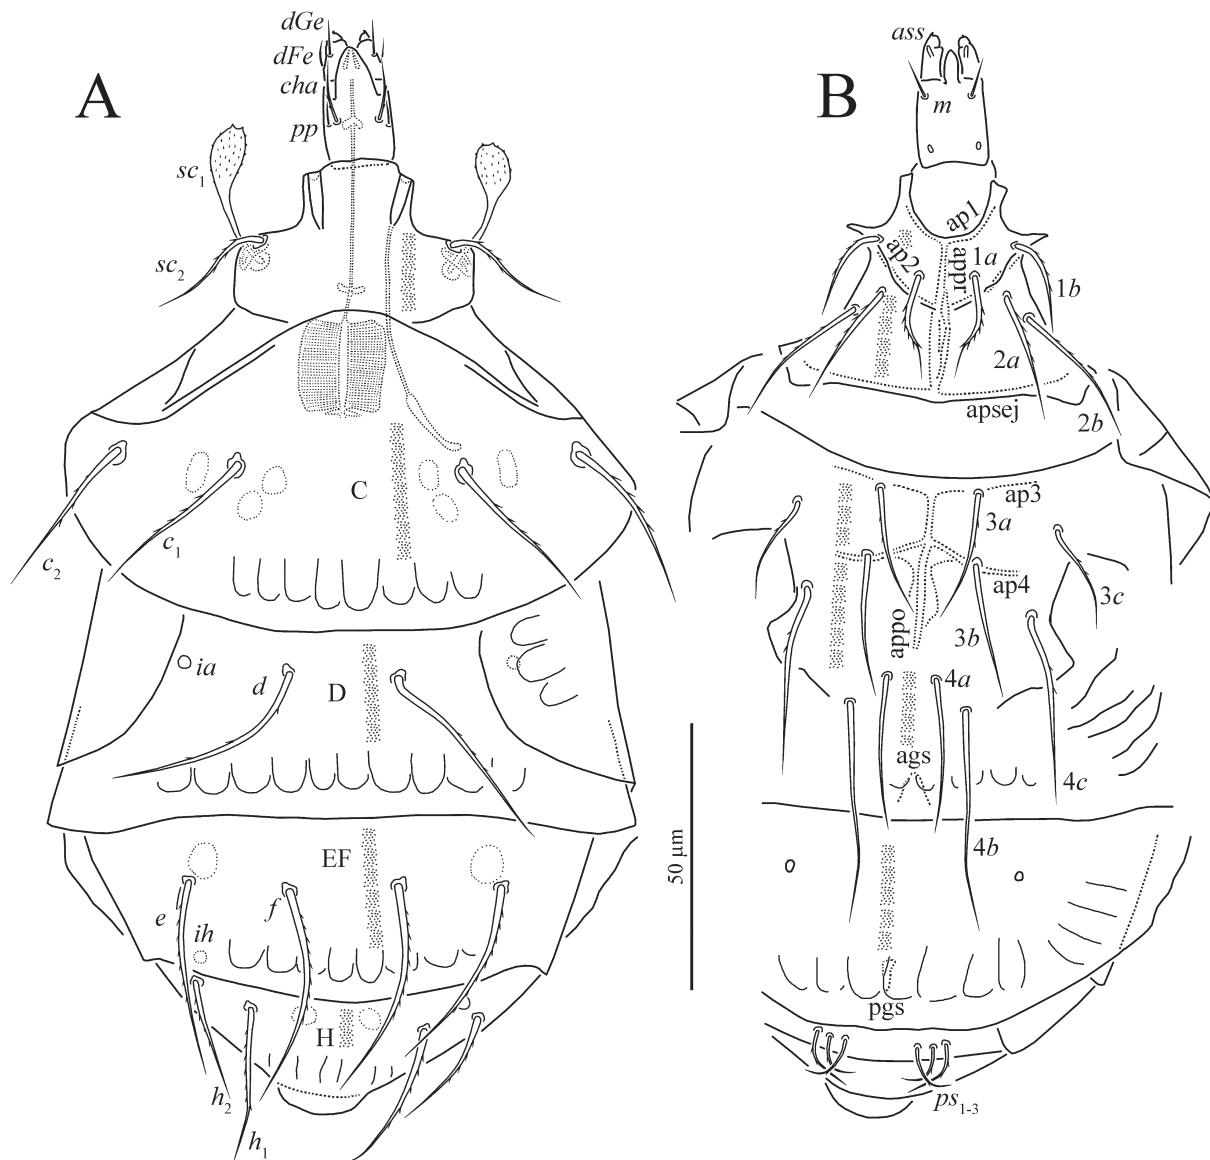

Fig. 1. *Neomicrodispus sibirensis* sp.n., female: A—dorsum of the body, B—venter of the body. Legs omitted.

Material examined. Female holotype (VR20100715) and one paratype found in a vial containing the beetle *Oryctes nasicornis* (Coleoptera: Scarabaeidae) and ethyl alcohol 75%. The host beetle was collected in Naharkhoran forest, Golestan Region, northern Iran, 36.46° N, 54.27° E, altitude 450 m., coll. V. Rahiminejad, 15 July 2010.

Remarks. Examination of the type material of this species revealed that it has the same setation of leg I as *N. sibirensis* sp.n. In the original description, only four eupathidia were depicted on tibiotarsus I. In fact, five eupathidia are present. Postpalpal setae are present (vs. absent in the original description). Trichobothria are barbed, with two short apical projections (vs. smooth and without projections in the original description). Setae e and

*h*₂ are weakly barbed (vs. smooth in the original description). Tibia IV is without solenidion, but with pore-like structure, visible on its typical insertion point (vs. with solenidion in the original description).
